

CS 523: Computer Graphics, Spring 2009

Shape Modeling

Surface deformation using
differential coordinates

Recap

Differential coordinates

- Detail = *smooth*(surface) – surface
- Smoothing = averaging

$$\delta_i = \frac{1}{A_i} \sum_{\mathbf{v}_j \in N_1(\mathbf{v}_i)} w_{ij} (\mathbf{v}_j - \mathbf{v}_i) \approx -H\mathbf{n}$$

Recap

Differential coordinates

- Represent ***local detail*** at each surface point
 - More descriptive of the shape than just xyz
- Linear transition from xyz to δ
- Useful for operations on surfaces where surface details are important

Recap

Laplacian matrix

- The transition between xyz and δ is linear:

$$\delta_i = \sum_{j \in N(i)} w_{ij} (\mathbf{v}_i - \mathbf{v}_j)$$

$$\begin{array}{l} \mathbf{L} \mathbf{v}_x = \delta_x \\ \mathbf{L} \mathbf{v}_y = \delta_y \\ \mathbf{L} \mathbf{v}_z = \delta_z \end{array}$$

Properties of the Laplacian matrix

- $\text{rank}(L) = n - c$ ($n - 1$ for connected meshes)
- We can reconstruct the xyz geometry from δ **up to translation**

$$\begin{array}{|c|} \hline L \\ \hline 1 \\ \hline \end{array} \begin{array}{|c|} \hline v_x \\ \hline \end{array} = \begin{array}{|c|} \hline \delta_x \\ \hline c_x \\ \hline \end{array}$$

$$\begin{array}{|c|} \hline L \\ \hline 1 \\ \hline \end{array} \begin{array}{|c|} \hline v_y \\ \hline \end{array} = \begin{array}{|c|} \hline \delta_y \\ \hline c_y \\ \hline \end{array}$$

$$\begin{array}{|c|} \hline L \\ \hline 1 \\ \hline \end{array} \begin{array}{|c|} \hline v_z \\ \hline \end{array} = \begin{array}{|c|} \hline \delta_z \\ \hline c_z \\ \hline \end{array}$$

Reconstruction

$$\begin{array}{c} \mathbf{L} \\ 1 \\ 1 \end{array} \mathbf{v}_x = \begin{array}{c} \delta_x \\ \mathbf{c}_x \\ \mathbf{e}_x \end{array}$$

$$\begin{array}{c} \mathbf{L} \\ 1 \\ 1 \end{array} \mathbf{v}_y = \begin{array}{c} \delta_y \\ \mathbf{c}_y \\ \mathbf{e}_y \end{array}$$

$$\begin{array}{c} \mathbf{L} \\ 1 \\ 1 \end{array} \mathbf{v}_z = \begin{array}{c} \delta_z \\ \mathbf{c}_z \\ \mathbf{e}_z \end{array}$$

Reconstruction

$$\begin{array}{c} \text{L} \\ \hline 1 \\ \hline 1 \end{array} \quad \mathbf{v}_x = \begin{array}{c} \delta_x \\ \hline \mathbf{c}_x \\ \hline \mathbf{e}_x \end{array}$$

$$\tilde{\mathbf{x}} = \arg \min_{\mathbf{x}} \left(\|\mathbf{L}\mathbf{x} - \delta_x\|^2 + \sum_{s=1}^k |x_k - c_k|^2 \right)$$

... and the same for y and z

Reconstruction

$$\begin{array}{c} \mathbf{L} \\ \hline 1 \\ \hline 1 \end{array} \mathbf{v}_x = \begin{array}{c} \delta_x \\ \hline \mathbf{c}_x \\ \hline \mathbf{e}_x \end{array}$$

$$\mathbf{A} \mathbf{x} = \mathbf{b}$$

Normal Equations:

$$\mathbf{A}^T \mathbf{A} \mathbf{x} = \mathbf{A}^T \mathbf{b}$$

$$\mathbf{x} = \underbrace{(\mathbf{A}^T \mathbf{A})^{-1}}_{\substack{\text{compute} \\ \text{once}}} \mathbf{A}^T \mathbf{b}$$

Details I left out

$$\begin{array}{|c|} \hline \mathbf{L} \\ \hline 1 \\ \hline 1 \\ \hline \end{array} \mathbf{v}_x = \begin{array}{|c|} \hline \delta_x \\ \hline \mathbf{c}_x \\ \hline \mathbf{e}_x \\ \hline \end{array}$$

$$\mathbf{A} \mathbf{x} = \mathbf{b}$$

Normal Equations:

$$\mathbf{A}^T \mathbf{A} \mathbf{x} = \mathbf{A}^T \mathbf{b}$$

$$\mathbf{x} = \underbrace{(\mathbf{A}^T \mathbf{A})^{-1}} \mathbf{A}^T \mathbf{b}$$

Actually, we won't compute the inverse (dense matrix, expensive). Instead we will factor $\mathbf{A}^T \mathbf{A} = \mathbf{M} \mathbf{M}^T$, \mathbf{M} is sparse and *triangular*

Matrix factorization

LU decomposition

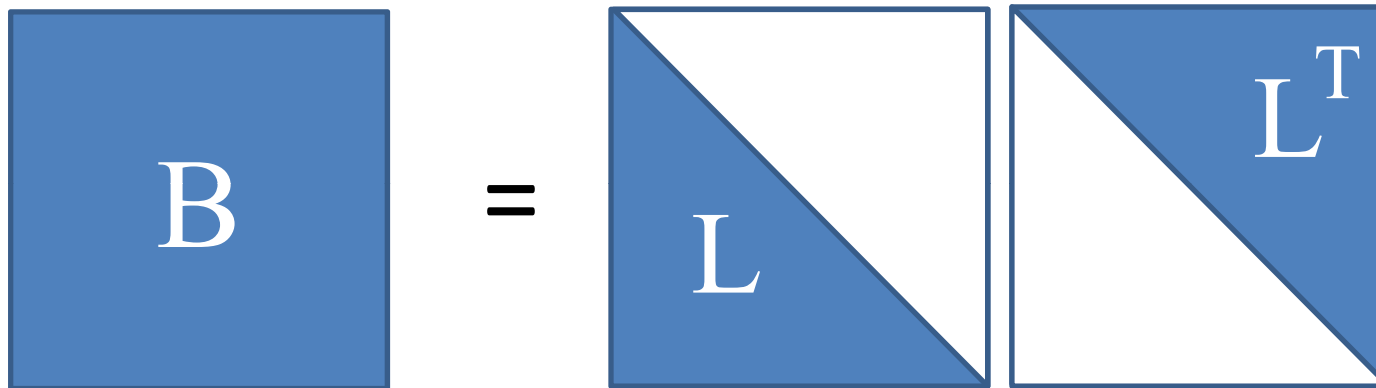

$$\begin{aligned} \mathbf{B}\mathbf{x} &= \mathbf{b} \\ \mathbf{L}(\mathbf{U}\mathbf{x}) &= \mathbf{b} \end{aligned}$$

$$\begin{aligned} &\longrightarrow \left. \begin{aligned} \mathbf{L}\mathbf{y} &= \mathbf{b} \\ \mathbf{U}\mathbf{x} &= \mathbf{y} \end{aligned} \right\} \end{aligned}$$

This is backsubstitution.
If L , U are sparse it is very fast. The hard work is computing L and U

Matrix factorization

Cholesky decomposition

The diagram illustrates the Cholesky decomposition of a matrix B . On the left is a solid blue square labeled B . To its right is an equals sign. Further right are two square matrices. The first is a lower triangular matrix labeled L , with a blue lower triangle and a white upper triangle. The second is an upper triangular matrix labeled L^T , with a white lower triangle and a blue upper triangle.

Cholesky factor exists if B is positive definite. It is even better than LU because we save memory.

Details I left out

$$\begin{bmatrix} \mathbf{L} \\ 1 \\ 1 \end{bmatrix} \mathbf{v}_x = \begin{bmatrix} \delta_x \\ \mathbf{c}_x \\ \mathbf{e}_x \end{bmatrix}$$

These should actually be high weights to ensure interpolation of the constraints. Or better yet, we can substitute the constraints directly into the LS system

$$\mathbf{A} \mathbf{x} = \mathbf{b}$$

Normal Equations:

$$\mathbf{A}^T \mathbf{A} \mathbf{x} = \mathbf{A}^T \mathbf{b}$$

$$\mathbf{x} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{b}$$

Differential coordinates for editing

- Intrinsic surface representation
- Allows various surface editing operations that preserve local surface details (normals, mean curvature)

Why differential coordinates?

- Local detail representation – enables **detail preservation** through various modeling tasks
- Representation with **sparse** matrices
- Efficient **linear** reconstruction

Editing framework

- The spatial constraints will serve as modeling constraints
- Solve the reconstruction equation every time the modeling constraints are changed

Detail constraints: $L\mathbf{x} = \delta$

Modeling constraints: $x_j = c_j, \quad j \in \{j_1, j_2, \dots, j_k\}$

$$\begin{array}{c} \text{L} \\ 1 \\ 1 \end{array} \begin{array}{c} \mathbf{v}_x \\ \\ \end{array} = \begin{array}{c} \delta_x \\ \mathbf{c}_x \\ \mathbf{e}_x \end{array}$$

Editing framework

- ROI is bounded by a belt (static anchors)
- Manipulation through handle(s)

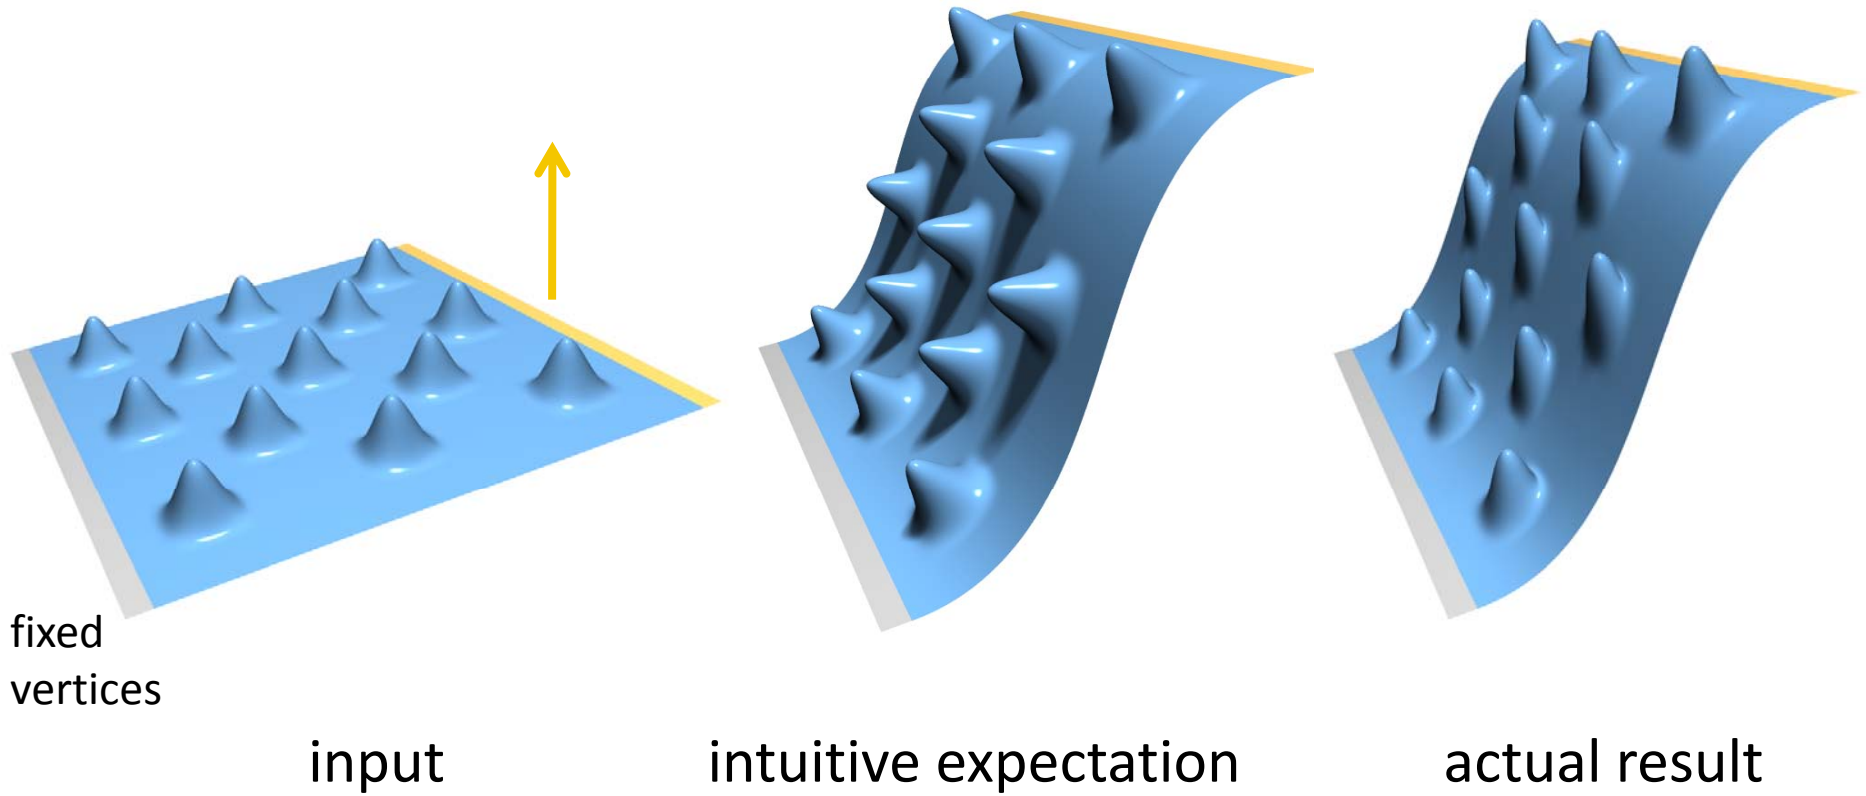

Fundamental problem: invariance to transformations

$$\Delta_M \mathbf{p} = -H\mathbf{n}$$

- The basic Laplacian operator is **translation**-invariant, but not **rotation**-invariant
- Reconstruction attempts to preserve the **original global** orientation of the details (the normal directions)

Fundamental problem: invariance to transformations

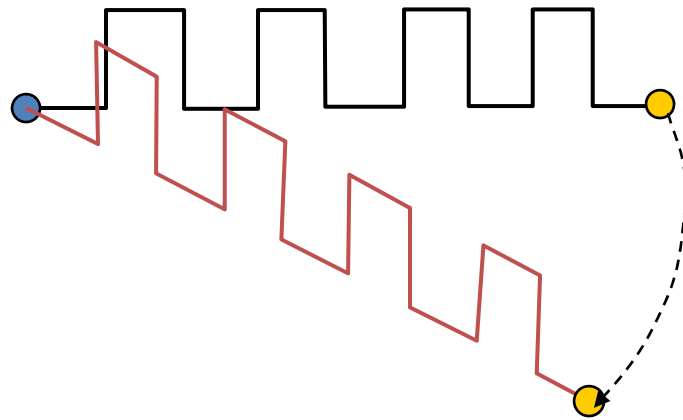

Fundamental problem: invariance to transformations

- The basic Laplacian operator is **translation**-invariant, but not **rotation**-invariant
- Reconstruction attempts to preserve the **original global** orientation of the details (the normal directions)

Fundamental problem: invariance to transformations

- The basic Laplacian operator is **translation**-invariant, but not **rotation**-invariant
- Reconstruction attempts to preserve the **original global** orientation of the details (the normal directions)

Fundamental problem: invariance to transformations

- Similar problem with the Great Wall of China...

Energy functional

- We posed this minimization problem (under handle constraints):

$$\arg \min_{\mathbf{x}} \left\| \Delta \mathbf{x} - \Delta \mathbf{x}_{org} \right\|^2$$

- But the rotated version of the original shape *is not a minimizer*. Need a rigid-invariant energy!

Fixing local rotations

Multiresolution framework

Discussion

- Advantages:
 - Fast! Linear solve for the base surface deformation, and then add back displacements
 - Intuitive, easy to implement
- Problem: works only for small height fields (details vectors are small)

almost a height field

not a height field

Multiresolution framework

Discussion

- Problem: If detail vectors too big we get overshooting and **self-intersections**, especially in concave cases

Local rotations – single res. solutions

- Come up with a rotation field on the surface based on the modeling constraints
- Rotate the differential coordinates; solve

Estimation of rotations

Lipman et al. 2004

- Reconstruct the surface with the original Laplacians δ (naïve Laplacian editing)
- Compute smoothed local frames, estimate rotation

Estimation of rotations

Lipman et al. 2004

- Reconstruct the surface with the original Laplacians δ (naïve Laplacian editing)
- Compute smoothed local frames, estimate rotation
- Rotate the δ 's and reconstruct again

Estimation of rotations

Lipman et al. 2004

- Advantages:
 - Sparse linear solve
 - Less or no self-intersections thanks to global optimization (no more local displacements that fight each other)
- Disadvantages:
 - Heuristic estimation of the rotations
 - Speed depends on the support of the smooth local frame estimation operator; for highly detailed surfaces it must be large
 - Unclear how much we need to smooth (what is detail?)

Rotation propagation

[Yu et al. SIGGRAPH 2004][Zayer et al. EG 2005][Lipman et al. SIGGRAPH 2005]

- Assume more user input: the user also specifies handle rotation
- The rotation is diffused to the rest of the ROI

Rotation propagation

- Geodesic distance [Yu et al. 2004]
- Harmonic field [Zayer et al. 2005]
- Optimization [Lipman et al. 2005, 2006]

Harmonic field

Harmonic fields on meshes

- Scalar function, attains 1 on the active handle, 0 on the static handles
- Smooth in-between, no local extrema
- Solve:

$$\Delta_M \mathbf{f} = 0$$

with constraints $f_i = 1$ on active handle,
 $f_i = 0$ on static handle

Example: in this simple case,
the harmonic field is a just a
linear ramp

Rotation propagation w/harmonic fields

Examples

Why does this happen?

Rotation propagation w/harmonic fields

Examples

- If rotations are provided and consistent with the desired transformation, this works well
- However, the method is translation-insensitive (doesn't generate rotations when there are none provided)

Optimization of rotation propagation

Lipman et al. 2005

- Keep a local frame at each vertex
- Prescribe changes to some selected frames (rotation/scaling)

Local frame:

$$\{\mathbf{a}_i, \mathbf{b}_i, \mathbf{n}_i\}$$

Optimization of rotation propagation

Lipman et al. 2005

- Reconstruction:
 - Encode the differences between adjacent frames – the numbers α β γ for each edge...
 - Solve for the new frames in least-squares sense

$$\mathbf{a}_i - \mathbf{a}_j = \alpha_1 \mathbf{a}_i + \alpha_2 \mathbf{b}_i + \alpha_3 \mathbf{n}_i$$

$$\mathbf{b}_i - \mathbf{b}_j = \beta_1 \mathbf{a}_i + \beta_2 \mathbf{b}_i + \beta_3 \mathbf{n}_i$$

$$\mathbf{n}_i - \mathbf{n}_j = \gamma_1 \mathbf{a}_i + \gamma_2 \mathbf{b}_i + \gamma_3 \mathbf{n}_i$$

... ..

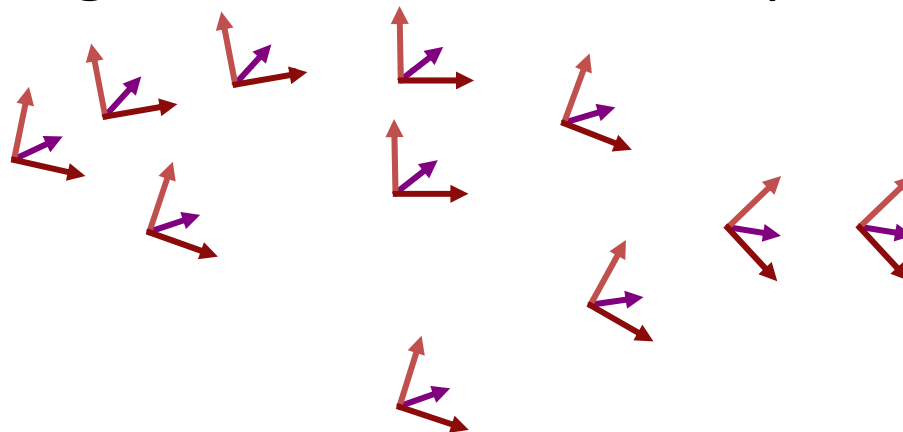

constraints

Optimization of rotation propagation

Lipman et al. 2005

- Reconstruction:
 - After having the frames, solve for positions

Optimization of rotation propagation

Lipman et al. 2005

- Reconstruction:
 - After having the frames, solve for positions

Optimization of rotation propagation

Lipman et al. 2005

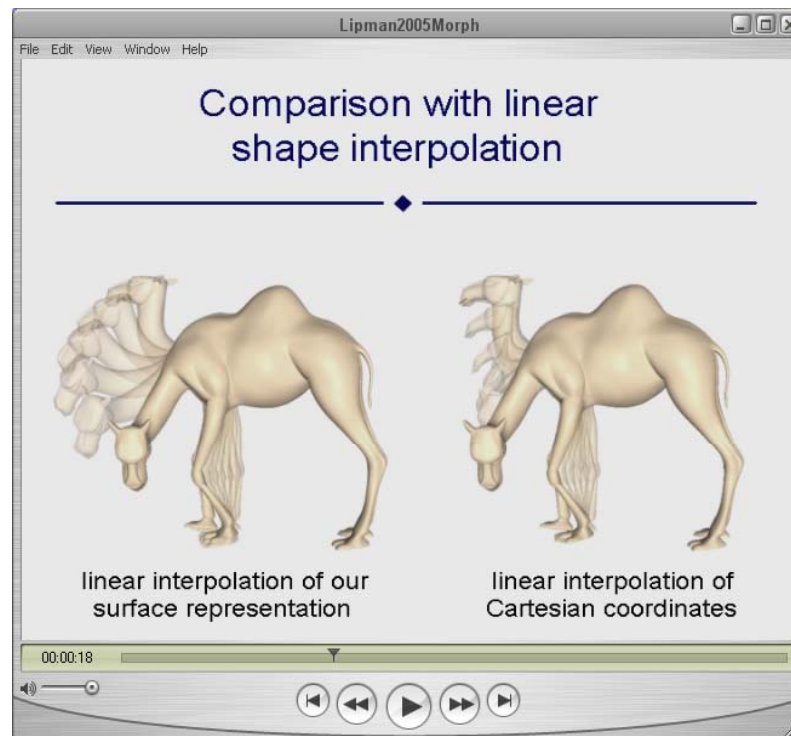

- Some results

Optimization of rotation propagation

Lipman et al. 2005

- Can use this representation for shape interpolation

Implicit definition of transformations

Sorkine et al. 2004

- The idea: solve for **local transformations** AND the edited surface simultaneously!
- Estimate the local transformations T_i from the eventual solution

$$\tilde{\mathbf{V}}' = \arg \min_{\mathbf{V}'} \left(\sum_{i=1}^n \left\| L(\mathbf{v}'_i) - T_i(\boldsymbol{\delta}_i) \right\|^2 + \sum_{j \in \mathcal{C}} \left\| \mathbf{v}'_j - \mathbf{c}_j \right\|^2 \right)$$

Transformation
of the local frame

Defining T_i

$$\tilde{\mathbf{V}}' = \arg \min_{\mathbf{V}'} \left(\sum_{i=1}^n \|L(\mathbf{v}'_i) - \mathbf{T}_i(\boldsymbol{\delta}_i)\|^2 + \sum_{j \in C} \|\mathbf{v}'_j - \mathbf{c}_j\|^2 \right)$$

- How to formulate T_i ?
 - Based on the local (1-ring) neighborhood
 - Linear dependence on the unknown \mathbf{v}'_i

$$\left\{ \begin{array}{l} \mathbf{v}'_{i_1} = T_i \mathbf{v}_{i_1} \\ \mathbf{v}'_{i_2} = T_i \mathbf{v}_{i_2} \\ \vdots \\ \mathbf{v}'_{i_k} = T_i \mathbf{v}_{i_k} \end{array} \right.$$

Defining T_i

- First attempt: define T_i simply by solving

$$T_i = \arg \min_{T_i} \sum_{j=1}^k \left\| \mathbf{v}'_{i_j} - T_i \mathbf{v}_{i_j} \right\|^2$$

$$\begin{pmatrix} T_i \end{pmatrix} = \begin{pmatrix} | & | & \dots & | \\ \mathbf{v}'_{i_1} & \mathbf{v}'_{i_2} & \dots & \mathbf{v}'_{i_k} \\ | & | & \dots & | \end{pmatrix} \begin{pmatrix} | & | & \dots & | \\ \mathbf{v}_{i_1} & \mathbf{v}_{i_2} & \dots & \mathbf{v}_{i_k} \\ | & | & \dots & | \end{pmatrix}^*$$

Defining T_i

- Plug the expressions for T_i into the least-squares reconstruction formula:

$$\tilde{\mathbf{V}}' = \arg \min_{\mathbf{V}'} \left(\sum_{i=1}^n \|L(\mathbf{v}'_i) - T_i(\boldsymbol{\delta}_i)\|^2 + \sum_{j \in C} \|\mathbf{v}'_j - \mathbf{c}_j\|^2 \right)$$

Linear combination
of the unknown \mathbf{v}'_i

But: we didn't solve anything since T_i is arbitrary affine transformation, i.e. admits distorting shears

Constraining T_i

- Rotation + scale (i.e., similarity) is easy in 2D:

$$T_i = \begin{pmatrix} s & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos \theta & \sin \theta & d_x \\ -\sin \theta & \cos \theta & d_y \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} w & a & t_x \\ -a & w & t_y \\ 0 & 0 & 1 \end{pmatrix}$$

- Can edit 2D curves:

Constraining T_i

- Rotation + scale (i.e., similarity) is easy in 2D:

$$T_i = \begin{pmatrix} s & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos \theta & \sin \theta & d_x \\ -\sin \theta & \cos \theta & d_y \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} w & a & t_x \\ -a & w & t_y \\ 0 & 0 & 1 \end{pmatrix}$$

- Applied in [Igarashi et al. 05] for 2D shape manipulation:

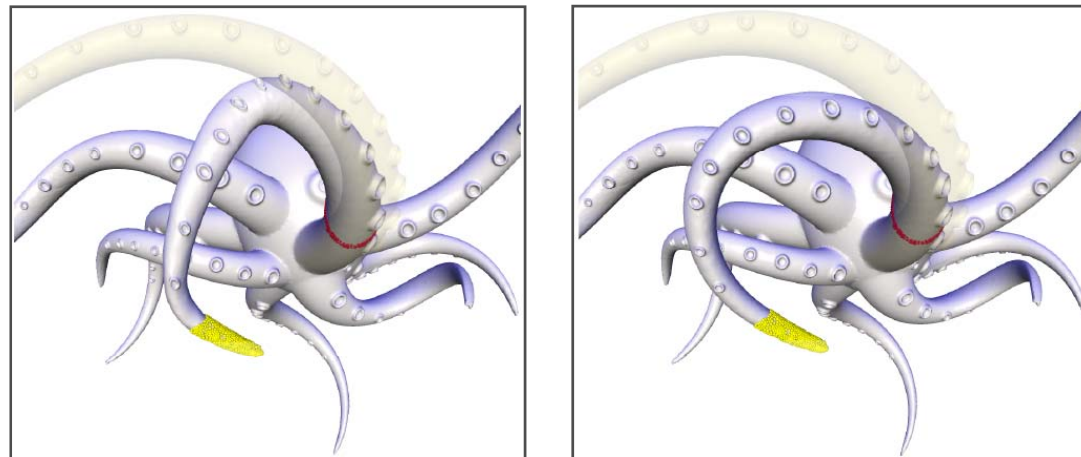

Defining the transformations T_i

- In 3D: have to linearize rotations

$$T_i = \begin{pmatrix} s & -h_3 & h_2 & t_x \\ h_3 & s & -h_1 & t_y \\ -h_2 & h_1 & s & t_z \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

- Works well for moderate rotations, problems with large rotation angles

Laplacian editing results

Detail transfer and mixing

- “Peel” the coating of one surface and transfer to another

Detail transfer and mixing

Examples

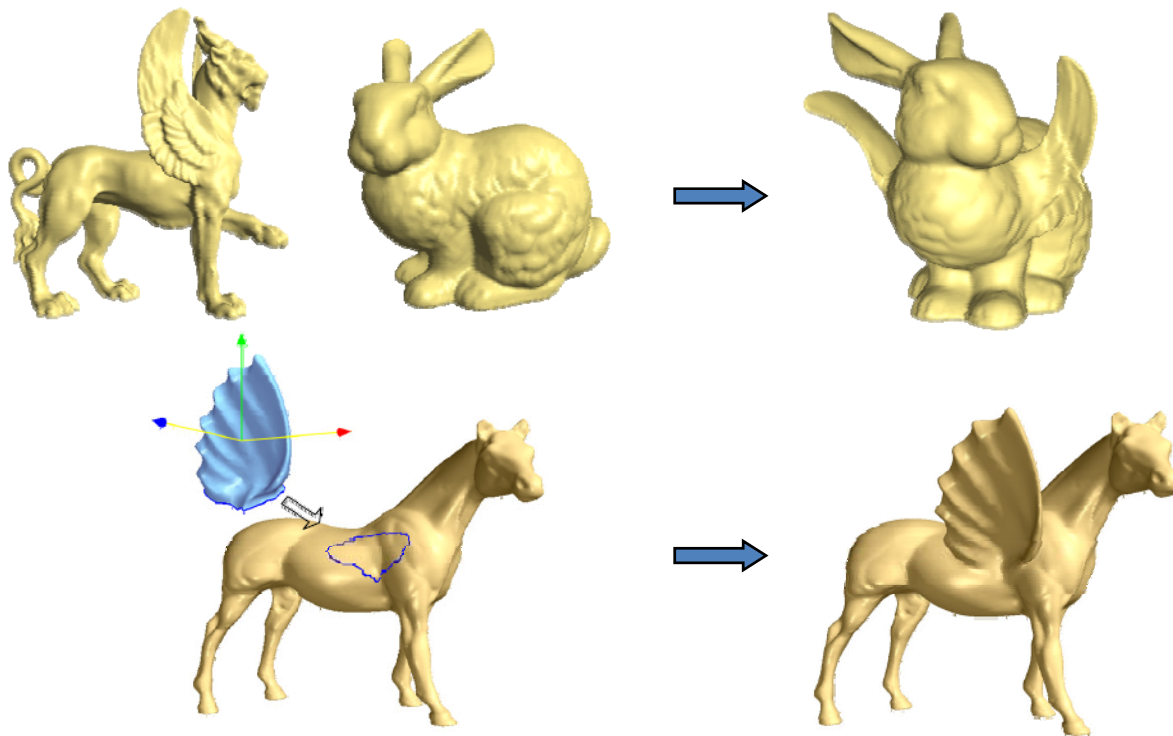

Detail transfer and mixing

Examples

Mesh transplanting

- Topological stitching
- Geometrical stitching via Laplacian mixing in a small area

Mesh transplanting

- Details gradually change in the transition area

Mesh transplanting

- Details gradually change in the transition area

Linear deformation methods

Summary

- Involve **linear** global optimization (efficient)
- Suffer from artifacts because of **local rotations**
- The relationship between the translation of a handle and the local rotation is inherently **nonlinear**

Nonlinear surface-based deformations

- Formulate a nonlinear functional that handles local rotations properly
- Still need an efficient method to minimize

$$\mathbf{p}' = \arg \min_{\mathbf{p}'} E(\mathbf{p}, \mathbf{p}')$$

As-rigid-as-possible surface deformation

Sorkine and Alexa 2007

- Smooth effect on the large scale
- As-rigid-as-possible effect on the small scale (preserves details)

Modeling ARAP detail preservation

- Previous work: Laplacian editing and its variants

$$\min_{\mathbf{v}'} \sum_{i=1}^n \|L(\mathbf{v}'_i) - R_i \boldsymbol{\delta}_i\|^2 \quad s.t. \mathbf{v}'_j = \mathbf{c}_j, j \in C$$

- Concentrated on making the optimization linear by “inventing” the right rotations or optimizing their linearized version

Direct ARAP modeling

- We actually may want to preserve the shapes of cells covering the surface

Direct ARAP modeling

- Let's look at cells on a mesh

Direct ARAP modeling

- Ask all the star edges to transform rigidly, then the shape of the cell is preserved

Direct ARAP modeling

- Cell energy: $\min \sum_{j \in N(i)} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i(\mathbf{v}_i - \mathbf{v}_j) \right\|^2$

Direct ARAP modeling

- If \mathbf{v} , \mathbf{v}' are known then R_i is uniquely defined

- It's the shape matching problem!

- Build covariance matrix $S = \mathbf{V}\mathbf{V}'^T$
- SVD: $S = \mathbf{U}\mathbf{\Sigma}\mathbf{P}^T$
- $R_i = \mathbf{U}\mathbf{P}^T$

R_i is a non-linear function of \mathbf{v}'

Direct ARAP modeling

- Can formulate overall energy of the deformation:

$$\min_{\mathbf{v}'} \sum_{i=1}^n \sum_{j \in N(i)} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i(\mathbf{v}_i - \mathbf{v}_j) \right\|^2$$

$$s.t. \mathbf{v}'_j = \mathbf{c}_j, j \in C$$

Energy minimization

- Alternating iterations

- Given initial guess \mathbf{v}'_0 , find optimal rotations R_i
 - This is a per-cell task! We already showed how to define R_i when \mathbf{v} , \mathbf{v}' are known

- Given the R_i (fixed), minimize the energy by finding new \mathbf{v}'

$$\min_{\mathbf{v}'} \sum_{i=1}^n \sum_{j \in N(i)} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i (\mathbf{v}_i - \mathbf{v}_j) \right\|^2$$

Energy minimization

- Alternating iterations

- Given initial guess \mathbf{v}'_0 , find optimal rotations R_i
 - This is a per-cell task! We already showed how to define R_i when \mathbf{v} , \mathbf{v}' are known

- Given the R_i (fixed), minimize the energy by finding new \mathbf{v}'

$$L\mathbf{v}' = \mathbf{b}$$

The big advantage

- Each iteration decreases the energy (or at least guarantees not to increase it!)
- The matrix L stays fixed!
 - Precompute Cholesky factorization
 - Just back-substitute each iteration (+ the SVD computations)

The importance of proper weighting

- If we use uniform Laplacian L

The importance of proper weighting

- The problem: need to compensate for varying shapes of the 1-ring

$$E_{cell} = \sum_{j \in N(i)} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i(\mathbf{v}_i - \mathbf{v}_j) \right\|^2$$

Use cotan weights

- Add cotangent weights [Pinkall and Polthier 93]

$$E_{cell} = \sum_{j \in N(i)} w_{ij} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i(\mathbf{v}_i - \mathbf{v}_j) \right\|^2$$

$$w_{ij} = \frac{1}{2} (\cot \alpha_{ij} + \cot \beta_{ij})$$

Use cotan weights

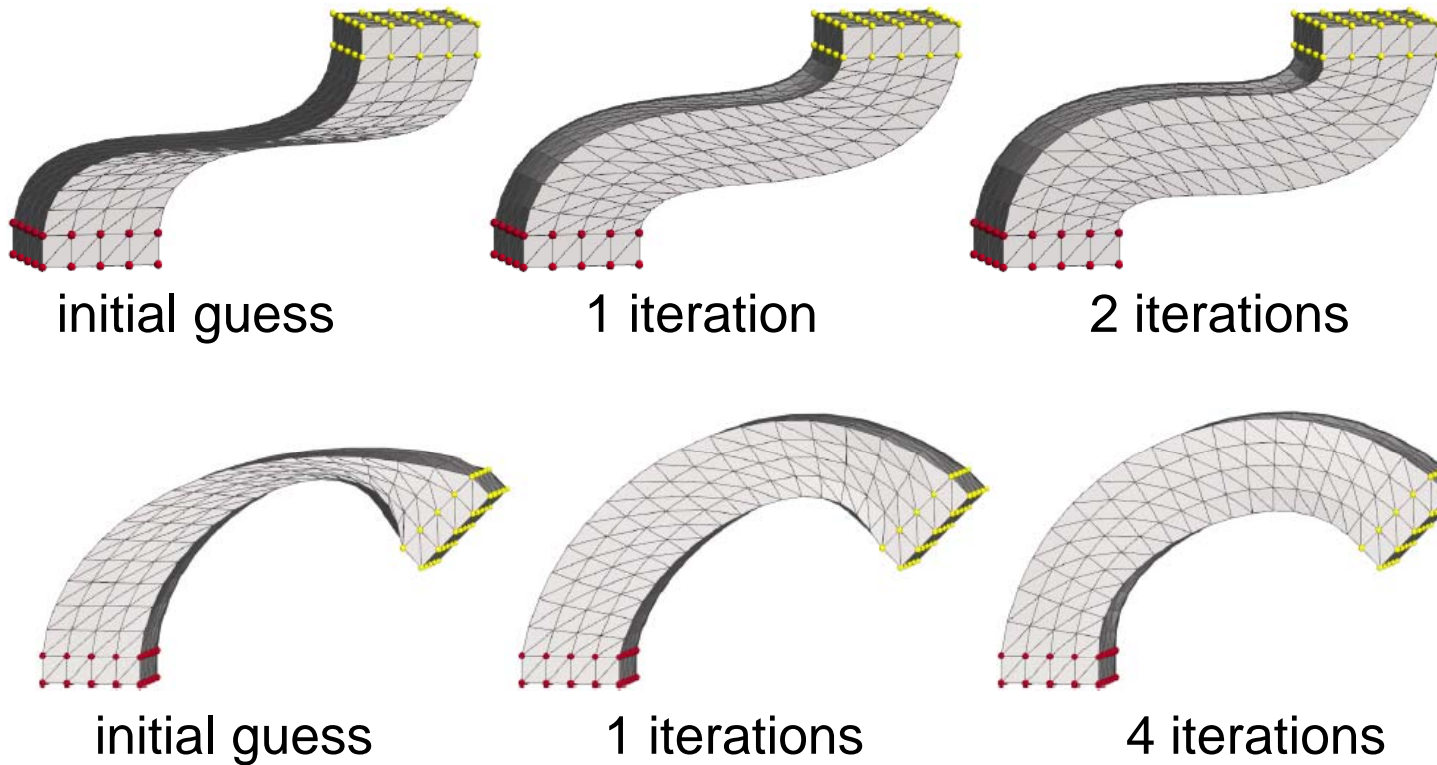

- This gives symmetric results

$$E_{cell} = \sum_{j \in N(i)} w_{ij} \left\| (\mathbf{v}'_i - \mathbf{v}'_j) - R_i(\mathbf{v}_i - \mathbf{v}_j) \right\|^2$$

Results

- Can start from naïve Laplacian editing as initial guess and iterate

Results

- Faster convergence when we start from the previous frame

Issues

- Works fine on small meshes
- On larger meshes: slow convergence
 - Each iteration is more expensive of course
 - Need more iterations because the conditioning of the system becomes worse as the matrix grows
- Implement multi-res strategy?
- Also: material stiffness depends on the 1-ring size (lots of wrinkles for fine meshes)

More issues

- This technique is good for preserving edge length (relative error very small)
- No notion of volume, however
 - Essentially, thin shells for the poor
- Can extend to volumetric meshes
